Healthy Eating Index (HEI) 2010 variables derived from food frequency questionnaire

The Healthy Eating Index (HEI 2010) is a measure of diet quality as assessed by compliance with the US Dietary Guidelines for Americans 2010.¹ SCCS FFQ data were linked with the USDA MyPyramid equivalents database to generate equivalent intakes for HEI food groups and calculate 12 component scores utilizing SAS code provided by the USDA.² Additional detail on the derivation of the HEI 2010 can be obtained in the references. Published work utilizing these variables must reference *Yu et al.* (reference 2).

Appendix: Investigator's Summary of Derived Physical Activity Variables

General information

Each participant was asked a series of questions about physical activity as part of the SCCS baseline interview. The exact wording of the questions can be found in the Baseline Codebook and the questionnaire posted on the SCCS website. The physical activity questionnaire evaluated a wide range of both active and sedentary behaviors done at home, work, and during leisure-time (sports/exercise). Questions about sedentary behaviors asked for the amount of time per day spent sitting: (a) in a car or bus, (b) at work, (c) watching TV or seeing movies, (d) using computer at home, and (e) for other reasons (e.g., sitting at meals, talking on phone, reading, playing cards, sewing). In terms of walking, time spent in slow (e.g., moving around, walking at work, walking the dog, light exercise) and fast walking (climbing stairs, walking to go places, or for exercise) was obtained. Time spent in light, moderate, and hard (vigorous) work at home and work were assessed for weekdays and weekend days separately. Examples of light (e.g., standing at work, light office work, shopping, cooking, child and elderly care) moderate (e.g., manufacturing work, shop work, cleaning house, gardening, mowing lawn, home repair), and vigorous (e.g., moving furniture, loading or unloading trucks, construction work, farming, or other hard labor) work were provided as hand cards during the interview. Information about the typical amount of time participants spent (per week) in moderate (e.g., bowling, dancing, golfing, softball) and vigorous (e.g., jogging, aerobics, bicycling, tennis, swimming, weight lifting, basketball) sports and exercise were also obtained. Historical activity levels in early adulthood ("in your thirties") for light, moderate, vigorous household and occupational work (per day), as well as moderate and vigorous sports/exercise (per week) were also assessed.

Variables to be used in analyses of physical activity were derived from the questionnaire responses. The variable names and definitions can be found in the Baseline Codebook in the section entitled 'Physical Activity Variables'.

Derived variables

Weekday and weekend averages

Weighted averages were used to calculate time spent in activities assessed on weekdays and weekends including sleeping, and current light, moderate, and hard work. Weekday values were assigned weights of 5/7 while weekend values were assigned weights of 2/7. If one of either the weekday or weekend value was missing, the non-missing value was assigned as the average. A flag indicating that the average was based on a single measurement was created (including Sleep_flag, LtWorkAvg1Var, ModWorkAvg1Var, and StrenWorkAvg1Var).

Outliers of questionnaire responses

Variables were set to the value of the 99th percentile if the raw value was greater than the 99th percentile value. The 99th percentiles for each variable were calculated from the entire SCCS cohort through December 20, 2006 (N=54,677).

Summary measurements

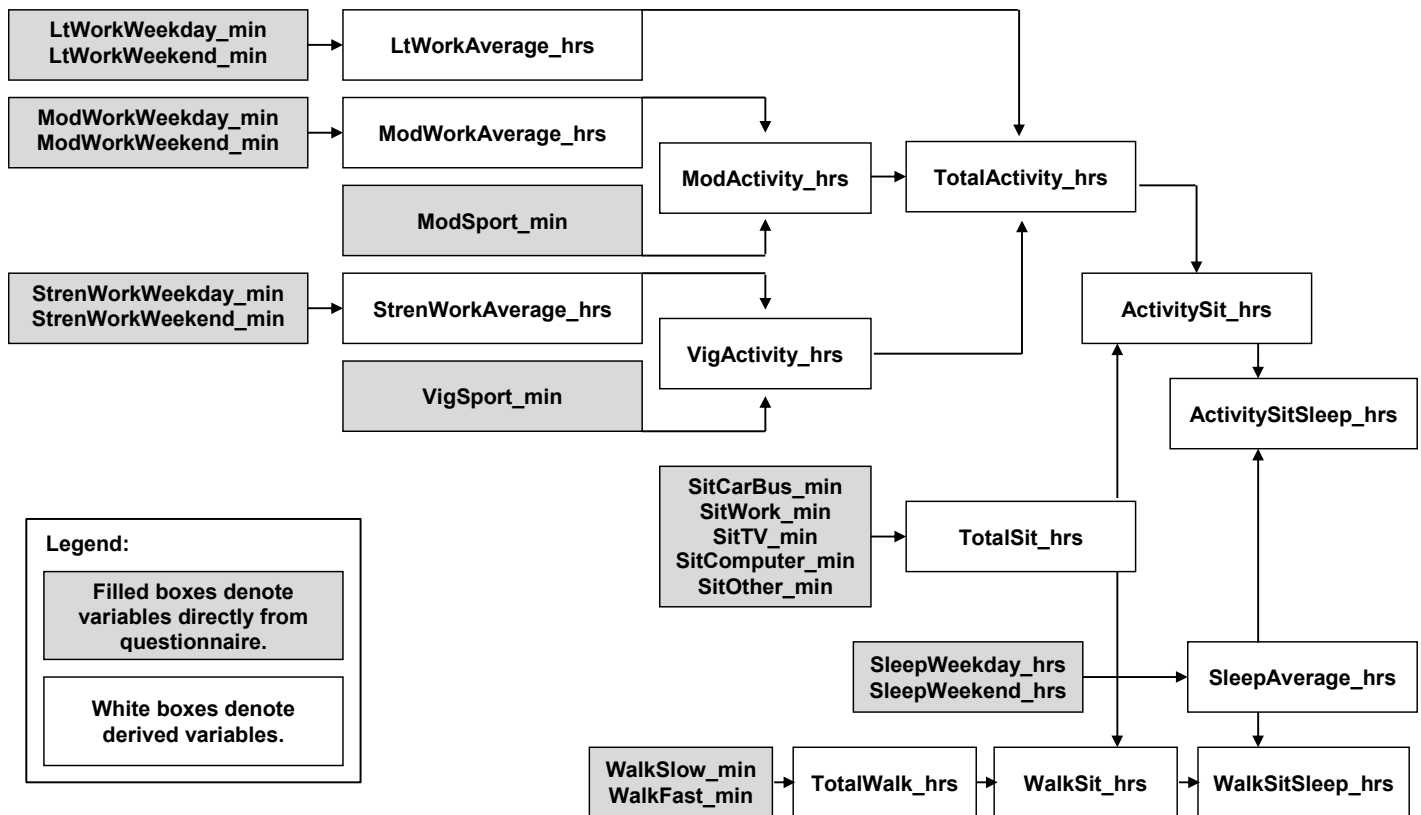

Derived physical activity variables were calculated as sums of multiple activities (see Figure 1). These summary variables include (a) total hours sitting, (b) total hours walking, (c) total hours of moderate activity (including moderate household/occupational work plus moderate sports), (d) total hours of vigorous activity (including hard household/occupational work plus vigorous sports), (e) total hours of activity (including all household/occupational work and all sports), (f) total activity plus sitting, (g) total activity plus sitting plus sleeping, (h) total walking plus sitting, and (i) total walking plus sitting plus sleeping. If **any** of

the components of these summary measures were missing in the questionnaire responses, the summary variable was defined as missing.

Outliers of derived variables

The 25th and 75th percentile values for the derived variable ActivitySit_hrs, ActivitySitSleep_hrs, WalkSit_hrs, WalkSitSleep_hrs, and TotalActivity_hrs were calculated based on the derived variable values calculated in the entire SCCS cohort through December 20, 2006 (N=54,677). Outlier detection defined by Tukey (Tukey, 1983) was used to define outliers at the upper range. Values were considered outliers if they were greater than the sum of the 75th percentile value and 1.5*the interquartile range; all outlier values were reset to the value of 99. In addition, a flag variable named with the prefix Outlier_ appended onto the variable name was created to have a value of 1 for any record which was determined to be an outlier by Tukey's method. Outliers at the lower range were considered to be values of 0 for the summary measures of activity plus sitting and walking plus sitting. Any record with a value of 0 for these derived variables had the value reset to 98 and an outlier flag variable created.

Figure 1. Summary Physical Activity variable derivation from questionnaire responses (gray cells) to derived variables (white cells).

MET calculations

In order to determine the energy cost of the physical activities reported, energy expenditure was estimated using standard metabolic equivalents (MET). Estimates for light, moderate, and vigorous activities were calculated as MET-hrs/d. These calculations were made using standard methods described in the Compendium of physical activity, which describes the energy cost of more than 600 different activity-related behaviors (Ainsworth, 2000). In addition, the series of manuscripts describing the development and evolution of the Compendium provides general guidelines for both selecting and applying MET values to survey data, as well as general organizational principles for specifying specific types and intensities of activity (Ainsworth, 1993 and 2000).

We used the following intensity descriptions for specific categories of activity on the survey (Table 1).

Table 1. Intensity descriptions and MET levels used in scoring the baseline SCCS questionnaire physical activity variables

Category	Intensity (MET range)
Sedentary behavior/inactivity	0.9 to 2.0
Light	2.1 to 2.9

Vigorous	≥ 6.0

To apply a specific MET level to each of the light, moderate, and vigorous activities in the SCCS questionnaire, representative activities from the Compendium were selected to reflect the types of activities listed on the handcards used during the interviews. The list of these select activities is presented in Appendix Table 1 (end of document). Appendix Table 1 includes the corresponding SCCS question in the first column and the activity code, MET value, major heading, and description of the selected activities from the Compendium in the subsequent columns. This list provides insight into the level of and variability of MET values within a given item on the questionnaire.

Appendix Table 1 and the Compendium in general were reviewed by a SCCS working group focused on physical activity scoring. By consensus, we selected specific MET values that were to be applied to each of the items in the baseline SCCS questionnaire. Questions for current activity levels and in early adulthood (“in your 30s”) were scored with the same MET values.

We elected to apply MET values only to the light, moderate, and vigorous activity items since they reflect energy expenditure that would be derived from purposeful ambulatory activity behaviors. In contrast, the energy cost of sedentary/inactive behaviors is minimal by definition (typically 1.0-1.5 METS) and is often considered independently of active behaviors (Dietz, 1996; Owen, 2000). Therefore, sedentary behaviors were described only in terms of duration (hrs/d) in the general scoring algorithm. Investigators that wish to estimate total energy expenditure (i.e., from sleep, sedentary, light, moderate, and vigorous activity) are encouraged to use 0.9 METS for sleep, and 1.25 METS for sedentary behaviors, along with the values calculated in the summary algorithm, to allow consistency within SCCS studies. The range of intensities for sedentary behaviors in Table 1 and the Appendix indicates a broader range of MET values than the conceptual definition above because of the variation in these values within the compendium for the same behavior (e.g., sitting and driving for transportation [2.0 METS] and sitting and driving at work [1.5 METS]).

In applying MET values to specific questions, some consideration was made for the most likely level of intensity in the context of the specific activity patterns being evaluated. For example, strenuous/vigorous activity done at home or work was given a MET value of 6.0 because such activities would be more likely to be done for longer durations and at slightly lower intensity levels. In contrast, vigorous sports/exercise was

given a MET weighting of 8.0 because these behaviors are often done at higher intensities, but for short duration. The MET values applied to the specific questions are described in Table 2.

Table 2. MET values applied to specific SCCS baseline questions

Question	MET value
Walking	
Slow	2.5
Fast	3.5
Household/Occupational work	
Light	2.3

Translation of MET-hrs/d into meaningful information

One MET is conceptually equivalent to the energy cost of resting metabolism, and multiples of this value (METS) are used to index the intensity of the specific activities. MET-hrs reflect the weighted average of the intensity (MET) and duration (hrs) of activity behaviors, and therefore describe the behavioral characteristics that lead to energy expenditure. In terms of caloric expenditure, 1 MET-hr is roughly equal to 1 kcal/kg/hr, for a person with a resting energy expenditure of about 60 kcal/hr or weighing 60 kg (Matthews, 2002). One MET-hr is also roughly equivalent to the energy expenditure associated with walking very briskly (4 METS) for 15 minutes (0.25 hrs). In certain applications, MET-hrs is a preferable index of energy expenditure because the units are independent of body weight (e.g., kcal/kg/d). In contrast, estimates of absolute expenditure (e.g., kcal/d) are dependent on body size. To estimate absolute energy expenditure values (kcal/d) using MET-hrs/d summary variables, the MET-hr/d value should be multiplied by an estimate of resting energy expenditure (kcal/hr) (Ainsworth, 1993).
